

DNS Overview

Karl Kranich, 5/23/2002

The basics

- Every machine on the Internet (also called a "host") has a hostname and at least one ip address
- the dns system translates hostnames to ip addresses. Many hostnames may point to a single ip address (this way we can have `www.yourdomain.com` and `www.abc.com` on the same web server with one ip address)
- the dns system also tells email servers where mail should be delivered for `users@yourdomain.com`
- So, dns servers just hold tables of information like:

```
www.yourdomain.com = 64.12.5.2
mail.yourdomain.com = 64.12.5.5
newsite.yourdomain.com = 64.12.5.9
yourdomain.com MX = mail.yourdomain.com
```

(`mail.yourdomain.com` is the "Mail eXchanger" for `yourdomain.com`)

What if I want to point `www.joesmith.com` to `www.yourdomain.com/joesmith`?

- `www.yourdomain.com/joesmith` identifies a host and a path to a directory on that host (the part after the slash)
- dns can only point hostnames (like `www.yourdomain.com`) to ip addresses. It knows nothing about directory paths
- to make this work, we need to use a combination of dns and web server configuration
- there are several ways to do this:
 1. Use dns to point `www.joesmith.com` to the same ip address as `www.yourdomain.com`. Then, use Host Headers or other "Virtual Site" features of the web server software to direct the `www.joesmith.com` browsing to the `joesmith` directory.
 2. Use dns to point `www.joesmith.com` to the ip address of some other web server. Use scripting and/or features mentioned above to redirect browsers to `www.yourdomain.com/joesmith`

DNS Lookup Process

(1) Web user with myISP.com needs to look up ip address for www.abc.com.
The user's computer sends a query to the myISP dns server.

myISP's dns server

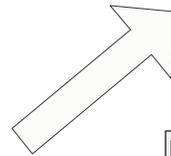

(5) myISP's dns server returns the ip address to the user

(2) myISP's dns server asks the main Internet dns servers, "where is the dns server for abc.com?"

root dns servers

(3) root dns servers say, "ask nameserver.abc.com"

nameserver.abc.com

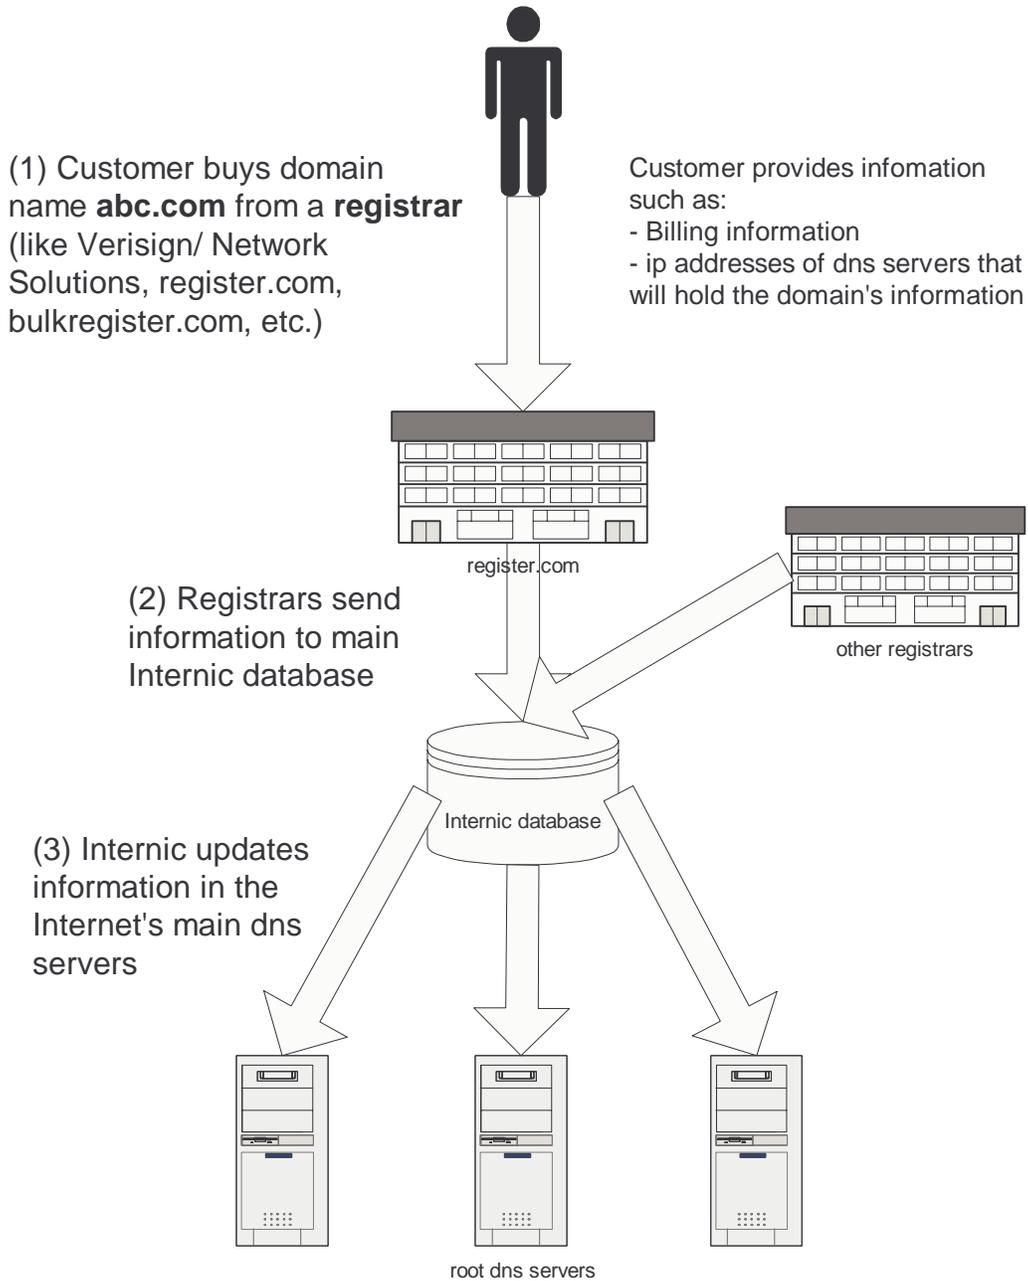

(4) myISP's dns server gets the address for www.abc.com from nameserver.abc.com

nameserver contains info like:

```
www.abc.com = 64.12.5.2  
mail.abc.com = 64.12.5.5  
newsite.abc.com = 64.12.5.9  
mail for users@abc.com should be  
directed to "mail.abc.com"
```

DNS Registration Process

root dns servers contain info like:

```
ccci.org queries should be referred  
to ns1.ccci.org  
abc.com queries should be referred  
to nameserver.abc.com
```
